Recent R&D Trends in Dye-Sensitized Solar Cells

<u>박남규*</u> 한국전자통신연구원 (npark@etri.re.kr*)

Dye-sensitized solar cell utilizing nanotechnology and photosynthesis attracts much attention due to its high solar-to-electricity conversion efficiency and low cost. This cell is based on high surface area nanostructured oxide film that is sensitized with dye molecules, which renders high solar-to-electrical energy conversion efficiency. Absorption of visible light by the dye leads to electron injection from the excited dye molecules to the conduction band of TiO2 via metal-to-ligand charge transfer process. The photo-injected electrons travel through the porous TiO2 network to the conducting oxide layer, thereby photocurrent is generated. The oxidized dye molecules are regenerated by iodide in the electrolyte, and the oxidized triiodide is reduced at the metal counter electrode to complete overall process. In this talk, recent R&D progress in dye-sensitized solar cell will be presented as well as its perspective.
